Assignment Topic

Review Report on ISO/IEC 12207 & Subsequent Specifications

Course Title: Software Project Management and Quality Assurance
Course Code: PMSCS 660

SUBMITTED TO

Dr. Mohammad Zahidur Rahman

Professor, Department of Computer Science and
Engineering

SUBMITTED BY

Md. Habibur Rahman

Id No: CSE202601013

Department of Computer Science and Engineering

Date: 05th June 2026

Technical Review Report: ISO/IEC 12207 and Modern software lifecycle Governance:

Objective:

The main goal of this report is to take a look at the ISO/IEC/IEEE 12207:2017 standard. We also want to see how it has been improved by complementary standards like ISO/IEC 24748, ISO/IEC 33000 series and ISO/IEC 27034.

This report also aims to propose a practical software engineering environment. These environments use development practices, DevOps automation, continuous automation and deployment pipelines and cloud native architecture.

At the time the framework must make sure that key software engineering principles like compliance, quality assurance, traceability and security are not compromised. So, this report focuses on balancing structured lifecycle governance with modern fast-paced development approaches.

Background:

ISO/IEC 12207 is one of the foundational standards in software engineering. It defines a framework for managing the entire software lifecycle starting from the initial idea and requirements gathering phase through development and testing and finally to deployment, operations, maintenance and system requirements.

The standard was first introduced in 1995 during a period when software development was mostly linear and followed waterfall methodologies. At that time software systems were generally built in defined phases, where each phase needed to be completed before the next one began.

Over time the software industry evolved significantly. ISO/IEC 12207 was updated according to 2008 revision: software lifecycle process with system engineering standards under ISO/IEC 15288 making it more suitable for integrated hardware-software systems.

2017 version: introduced a flexible outcome-based

and methodology-neutral approach. This version allowed organizations to apply the standard in agile, iterative or hybrid development environments.

Because of this ISO/IEC 12207 standard alone is not enough. It must be supported by standards that extend its capabilities and make it more practical for real-world modern software engineering.

Overview of ISO/IEC 12207 standard:

ISO/IEC/IEEE 12207:2017 defines a structured framework for managing software lifecycle processes. Its main purpose is to ensure that software development is systematic, traceable and controlled from beginning to end.

The standard organizes all software lifecycle activities into four process groups:

1. Agreement processes: Agreement processes define formal relationships between organizations involved in software development such as customers, suppliers, vendors and contractors. These processes ensure that both parties clearly understand their responsibility, expect-

-tations and deliverables.

The main components includes:

Acquisition process: This process involves identifying business needs defining systems requirements evaluating suppliers, selecting vendors and managing contracts throughout the project lifecycle. It ensures that the acquiring organization receives the product or service according to defined expectations.

supply process: This process defines how supplier delivers software products. It ensures that suppliers follow agreed requirements maintain quality standards and deliver systems that meet obligations.

2. organizational project-Enabling processes:

These process support the organization rather than individual projects. Their goal is to create an efficient environment where all software projects can operate effectively.

Key components include:

Lifecycle model management: Defines, maintain life-

-cycle models used across different projects depending on their nature.

Infrastructure management: provides tools, development environments, servers and platform required for software development.

Project portfolio management: Ensures that projects are selected and prioritized based on business value and strategic goals.

Human resource management: Focuses on hiring, training and development software engineering teams.

Quality management: Establishes quality standards, policies and continuous improvement mechanisms across the organization.

3. Technical management process:

Technical management process ensure that software projects are properly planned, monitored and controlled throughout their execution.

These process includes:

Project planning: Define scope, timeline, cost

estimation and resource allocation.

Project control: Monitors project progress and takes corrective actions when deviation occurs.

Decision management: Ensures that technical and business decisions are made systematically based on data and analysis.

Risk management: Controls changes in software artifacts, versions and system configurations.

Information management: Ensure documentation storage, distribution of project related information.

Quality Assurance: Verifies that process and outputs comply with defined standards.

4. Technical processes: Technical processes from the core engineering activities of software development. They describe how business needs are transformed into working software system.

They include,

- Requirements Definition
- System Architecture Design.
- Detailed Design.

- Implementation
- Integrations of components.
- Verification
- Validation
- Deployment
- Operations and maintenance
- system disposal and or Retirement

Critical Evaluation of ISO/IEC 12207

Strengths:

ISO/IEC 12207 provides important strengths that make it a foundational standard in software engineering.

First, it offers complete lifecycle coverage meaning it includes all stages of software development from initiation to retirement. This ensures that no critical phase is overlooked.

second, it provides a terminology which improves communication between developers, managers, clients and auditors.

Third, it ensures that quality and consistent development practices by defining structured processes that organizations can follow.

Fourth, it is highly suitable for large scale enterprise systems, especially where multiple teams and vendors are involved.

Limitations:

Despite its strengths ISO/IEC 12207 has limitations in modern software environments.

One major limitation is compatibility with Agile and DevOps practices, which rely on continuous iteration and rapid feedback rather than fixed phases.

Another issue is the heavy documentation requirement, which often slows down development and increases workload especially for small and medium-sized organizations.

Extended and complementary standards:

To overcome these limitations several modern standards to extend ISO/IEC 12207

1. ISO/IEC 24748:

ISO/IEC 24748 helps organizations adapt lifecycle processes to modern development environments.

It enables:

Mapping structured lifecycle processes into frameworks like Scrum and Kanban
replacing heavy documentation with lightweight evolving artifacts such as user stories and product backlogs.

2. ISO/IEC 33000 series:

The ISO/IEC 33000 series focuses on evaluating and improving software development processes over time.

It provides,

- measurement of process performance
- capability and maturity assessment models
- continuous improvements framework.
- Organizational benchmarking tools.

2

3. ISO/IEC 27034: ISO/IEC 27034 integrates security directly into the software development lifecycle.

It introduces,

- Organizational normative framework
- project normative framework
- Application security controls.
- security is applied throughout the lifecycle using practices such as:
 - a. Threat modeling during requirement analysis.
 - b. Architecture design.
 - c. Static and dynamic code analysis.
 - d. Continuous vulnerability scanning in CI/CD pipelines.

Integrated software Governance framework

A modern organization can combine ISO/IEC 12207 with ISO/IEC 24748 ISO/IEC 33000 and ISO/IEC 27034 to form governance model.

3

In this integrated model,

- ISO/IEC 12207 defines the lifecycle structure
- ISO/IEC 24748 enables Agile Adaptations.
- ISO 33000 provides process measurement and improvement.
- ISO 27034 ensures security integration

In this approach:

- Requirements are managed through Agile backlogs
- Development happens in CI/CD pipelines.
- Automated testing ensures quality.
- Security tools scan every code change.
- Deployment logs automatically serve as audit evidence.

Organizational Implementation Strategy:

For sized organizations implementation can be done step by step:

Step 1: Establish organization normative Framework.

Step 2: Organizations define standard policies such as:

- coding standard
- security guidelines..
- Approved tools and libraries.
- Infrastructure templates.

Step 2: Agile Align processes:

Map lifecycle processes, into Agile practices:

- planning → sprint planning.
- monitoring → Daily standup.
- Reviews → Sprint reviews.

Step 3: Implementation CI/CD Automation:

Automate key proccers:

- Unit testing
- code quality checks.
- security scanning.
- dependancy validation.

Step 4: Define strong Definition of Done:

A feature is done only complete when:

- All tests pass
- code review is approved.

- Deployment is successful.

Benefits of Integrated Approach:

The Integrated governance model provides important benefits:

- Software delivery is now faster and more efficient.
- The security of lifecycle is stronger.
- We have reduced the effort that goes into documentation.
- This makes us better at compliance and getting ready for auditors.
- Our work is now more in line with agile and DevOps practices.
- We can scale for cloud native systems.

Conclusion:

- The standard for software engineering is still ISO/IEC 12207.
- It gives us a systematic way to manage the software lifecycle.
- Modern software development needs to be

more flexible

- it needs automation and continuous delivery.

When we use ISO/IEC 24748 and ISO/IEC 33000 and ISO/IEC 27034 together we can create a framework for software governance.

This framework balances discipline with the flexibility of Agile and awareness of security.

This approach lets us have compliance-as-code.

Governance is now part of automated pipelines. It is not handled manually anymore.

In the end the future of software engineering governance is about combining lifecycle management with automation and Agile methodologies and strong security.

This means software engineering governance will be about software lifecycle management and automation and Agile methodologies and security.

The future is, about software lifecycle management and automation and Agile and security.
