

Basic Structure (Boilerplate)

Every program has an "Entry Point" where execution begins

C++

```
#include <iostream>
using namespace std;

// Entry Point
int main() {
    cout << "Hello";
    return 0;
}
```

Java

```
public class Main {
    // Entry Point
    public static void main(String[]
        args) {
        System.out.println("Hello");
    }
}
```

Python

```
# No boilerplate needed!
# Script executes top-to-bottom
print("Hello")
```

Note: C++ and Java require a specific function ('main') to start.

What is a Variable?

Definition:

A **Variable** is a named storage location in the computer's memory (RAM) that is used to store a value.

Box Analogy (Easy Understanding):

- **Label Name** → Variable Name (e.g., age)
- **Contents** → Stored Value (e.g., 25)
- **Box Size** → Data Type (e.g., Integer)
- **Address** → Memory Location (e.g., 0x104A)

Identifiers (Naming Variables)

Definition:

An **Identifier** is the name given to a variable, function, or class.

The 3 Golden Rules

- 1 Can contain **Letters** (A-Z, a-z), **Digits** (0-9), and **Underscores** (_).
- 2 Must **NOT** start with a digit. (e.g., 1stPlace is illegal).
- 3 Must **NOT** be a Keyword (reserved word like int, class, if).

Valid	Invalid	Reason
studentAge	student Age	Contains space
grade_1	1stGrade	Starts with number
_total	float	Reserved keyword
